Abstract. About 37 thousand people die per year in Europe due to infections by resistant bacteria. Fighting antimicrobial resistances (AR) is a top priority to save lives and reduce costs. AR is triggered mostly by uncritical antibiotic prescription. This paper presents HAITool, a decision-making information system to support antibiotic prescription. The system was co-developed together with health professionals using Design Science Research Methodology, empowered with innovative data visualization techniques to improve AR management. HAITool includes integrated visualizations of patient, microbiology, and pharmacy data, facilitating clinical decision support, antibiotic prescriptions quality and antibiotic-resistant bacteria monitoring. It also includes an alert module that monitors conformance of antibiotic prescriptions with norms and guidelines. HAITool is evaluated using both the Österle principles and interviews with physicians and infection control team from three participant hospitals.

Keywords. Computer-Assisted Medical Decision Support System, design science research methodology, co-design, Antibiotic prescription, Antibiotic Stewardship

1. Introduction

Healthcare-associated infections (HAI) are one of the major worldwide causes of death and disability, with an important economic impact of several billion dollars/year in the USA [1]. Antimicrobial resistance (AR) increase even more morbidity, mortality and costs associated with HAI [2]. Antibiotic (AB) misuse is at the heart of AR: uncritical AB prescription leads to the development of antimicrobial resistant bacteria [3]. Antimicrobial resistant HAI can be addressed by interventions reducing unnecessary AB prescribing [4]. However, infection control team spend most of their time on data collection, suspected cases finding, medical records review, etc., and it is hard for them to have time for dealing with proactive preventive activities [5]. This problem can be tackled with computerized surveillance and decision support systems, which have

1 Corresponding Author: luis.lapao@ihmt.unl.pt
proven to be effective in the prescription errors reduction, medical care improvement and compliance with recommendations [6]. These systems will not replace clinical judgement. Their purpose is to increase the information available, so healthcare professionals can improve the decision process [7]. HAI surveillance, clinical decision support, overviews of complex matters, alerts, and reminders have an added value [8]. Antibiotic Stewardship Programs (ABS) have been developed to decrease prevalence of AR. ABS could contribute to the optimization of antibiotic prescription, promoting the adequate use (e.g. dose and duration) and reducing costs [3]. Clinical decision support systems (CDSS) are playing an increasingly important role in providing recommendations. The integration of CDSS into electronic health records has been shown to improve the quality of care and to enhance patient outcomes [9]. Interactive and integrated data visualization could increase the understanding of a patient’s infection status and enhance AB decision-making [10].

2. Methods

This paper presents HAITool, a surveillance and clinical decision support system expected to contribute to reduce antibiotic misuse and resistance. The project was conducted using Design Science Research Methodology (DSRM) which establishes a six-stage process, namely problem identification, objectives definition, design and development, demonstration, evaluation, and communication [11]. In this research case we propose an instantiation (i.e. software).

3. Proposal

In this section the HAITool research and co-design objectives are presented.

3.1. Objectives

The objectives of this research are the following:

- Monitoring AB consumption - updated data on AB consumptions is relevant for monitoring antimicrobial resistance.
- Monitoring AB resistant bacteria - updated data on AB resistant bacteria rates is important to follow trends and detect outbreaks.
Promote AB prescription based on guidelines - to have an integrated view of patient-data and alerts-based on guidelines eases AB prescriptions.

3.2. Design

HAITool is a web-based information system supported by a SQL Server (2012) database which combines and stores pharmacy, microbiology, and patient-related information (Fig. 1). The current Extract-Transformation-Load (ETL) module is written in Java. Regarding data visualization, Qlik Sense is used (with some extensions). Qlik Sense is the newest release from Qlik, which is also the company owning QlikView, that have already been used within several healthcare research contexts [12].

4. Demonstration

HAITool’s demonstration took place in an Intensive Care Unit (8 beds), in a tertiary Portuguese hospital. The research objectives were successfully achieved: HAITool correctly portrayed data allowing infection control team to discover AB consumption levels, rates of AB resistant bacteria and conformance of AB prescriptions.

One of the main features of the solution is the visualization of AB resistance patterns through simple and clear graphs (Figure 2). The information can be further filtered by microorganism and ward, which facilitates the visualization. For instance, color green shows AB for which no cases of resistance were found in a specific organism, informing physicians about which AB is more likely to treat the suspected microorganism in the specified ward. In situations where AR is found, the AB is portrayed by a red color in the diagram indicating that the AB will not treat the patient. Intermediate resistance is represented by the orange color. In cases where the microorganism is resistant to an AB in a patient but susceptible in another one, the AB appears blue. This visualization also allows to filter by patient, which means that it is possible for the physicians and infection control team to see the antibiogram results for each and every patient that is (or was) hospitalized.

Other HAITool’s feature is AB consumption. Concerning microorganism’s monitoring, HAITool allows users to understand the distribution of AB resistant bacteria by ward. Other feature, the patient’s timeline is an integrated view of relevant patient events, providing information on data such as vital signs, microbiology laboratory results, AB consumption and surgery. For instance, a common timeline has often four sections, namely: length of patient stay, clinical analysis events, antibiotics consumption, and alerts for ESKAPE+C microorganisms isolation and AB not in conformance with guidelines. The patient’s timeline has appended some vital signs (eg, temperature, blood pressure and CRP), describing variations in the patient condition. All features are the result of interactions with physicians and infection control team and are expected to facilitate the clinical decision support process, as well as to contribute to the reduction of antibiotics overuse and misuse. HAITool audit module (that deals with AB prescriptions based on guidelines) appears on patient’s timeline and on the main page of infection control team, and includes alerts on: AB duration, prescription and surgery prophylaxis AB. These kind of alerts has been described elsewhere as effective [13]. HAITool alerts were made based on Portuguese guidelines [14].
5. Evaluation

HAITool evaluation was based on interviews with physicians and infection control team, as well as by using Österle principles. Interviews evaluated the first cycle of design and implementation of HAITool. Structured interviews [15] were supported by a pre-elaborated survey. The overall survey answers indicated that HAITool is “very ++useful” on preventing and control AR by providing AB resistant patterns, AB consumption rates, enhance the communication between infection control team, microbiology laboratory, physicians and pharmacists, as well as the relevance of alerts on AB prescriptions compliance with norms. Design-oriented information system research must follow four basic principles: abstraction, originality, justification and benefit, also known as principles of Österle [16]:

- **Abstraction**: HAITool may be used by physicians and infection control team to tackle AB misuse at both public and private hospitals. Its data requirements are commonly available in any hospital.

- **Originality**: HAITool was designed by a multidisciplinary team including healthcare professionals, contributing to the creation of a system oriented to their real needs. HAITool is supported by Qlik Sense, the newest product provided by Qlik.com.

- **Justification**: According to WHO, HAI are a major worldwide cause of death [1]. HAITool is an information system to help prevent, manage and control HAI that was validated by physicians and infection control team.

- **Benefit**: It benefits health organizations and the society at large by providing an integrated view on patient and facilitating the work of physicians and infection control team. It also contributes to more informed empirical AB prescriptions, once it allows physicians to check AB resistance, speeding up the decision process.

6. Conclusion

We have validated HAITool with physicians and infection control team in what concerns HAI’s prevention, management and control. Still, we are not yet able to confirm that the use of the system reduces AB misuse and AR levels. HAITool was debated in the Annual Meeting on Infection Control and Antimicrobial Resistance.
with an attendance of more than 30 healthcare professionals, including the hospital administrator, physicians, nurses, researchers, and infection control team. Besides, HAITool internet portal and periodical reports to hospitals are also enforcing the communication of the research results. We believe that HAITool achieved the research objectives, according to the current feedback from healthcare professionals. The next step is measuring the impact of AB consumption and prescription compliance with the norms, alerts effectiveness, bacteria resistances and costs. We are also studying the adherence of physicians and infection control practitioners to HAITool.
